

EXECUTIVE RESEARCH REPORT: CRYPTOCURRENCY PORTFOLIO & RISK ANALYSIS

12-Month Performance Trajectory, Volatility Evaluation & Strategic Allocation Framework

Author / Analyst:	A. Mohammed Aslam	Internship Track:	Finance & Investment Analysis (CodeAlpha)
Analysis Period:	July 28, 2025 – July 28, 2026 (Daily Data)	Primary Currency:	Indian Rupees (INR / ₹)

1. Executive Summary & Research Objectives

This report delivers a rigorous quantitative examination of the 12-month performance and risk profiles of three leading digital assets: **Bitcoin (BTC)**, **Ethereum (ETH)**, and **Solana (SOL)**. Over the analyzed period from July 2025 to July 2026, the broader cryptocurrency market experienced a macro consolidation cycle characterized by monetary tightening pressures, ETF inflow normalization, and risk-off sentiment across speculative technology sectors.

The objective of this analysis is to evaluate capital preservation characteristics, comparative drawdown risks, and volatility differentials to formulate a robust **risk-adjusted portfolio allocation framework** for institutional and retail investors.

2. Comparative 12-Month Performance Table

Asset Name	Starting Price (INR)	Ending Price (INR)	1-Year Return (%)	52-Week High (INR)	52-Week Low (INR)
Bitcoin (BTC)	₹10,351,153.20	₹6,247,126.18	-39.65%	₹11,031,645.85	₹5,639,316.42
Ethereum (ETH)	₹336,552.53	₹186,476.72	-44.59%	₹419,789.14	₹146,702.79
Solana (SOL)	₹16,378.28	₹7,337.56	-55.20%	₹21,815.44	₹5,904.60

Key Analytical Takeaway: Macro Resilience vs. Altcoin Volatility

While all three assets generated negative absolute returns over the 1-year window, **Bitcoin demonstrated superior capital preservation** with a -39.65% drawdown, outperforming Ethereum by nearly 500 basis points and Solana by over 1,550 basis points. This confirms BTC's role as the primary defensive anchor in digital asset portfolios during macroeconomic drawdowns.

3. Visual Performance & Historical Trajectory Analytics

4. Deep-Dive Risk & Volatility Evaluation

Evaluating digital assets strictly on nominal returns obscures their underlying risk profiles. By analyzing the 52-week price extremes and normalized daily fluctuations, three distinct structural behaviors emerge:

Bitcoin (BTC): Defensive Store of Value

Bitcoin traded within a 52-week range of ₹5.63M to ₹11.03M. Despite dropping 39.65% from start to finish, BTC maintained strong institutional support

Ethereum (ETH): Moderate Layer-1 Beta

Ethereum experienced a 44.59% contraction, trading between ₹146.7K and ₹419.8K. While ETH suffered from cyclical DeFi deleveraging, its

above its ₹5.63M floor. Its lower standard deviation of daily returns makes it the lowest-beta asset in the cryptocurrency ecosystem.

drawdown was significantly cushioned compared to smaller-cap smart contract platforms, maintaining liquidity as the industry's premier settlement layer.

Solana (SOL): High-Beta Asymmetric Volatility

Solana recorded the most severe decline at **-55.20%**, collapsing from a peak of ₹21,815.44 to a 52-week low of ₹5,904.60. SOL exhibits high sensitivity (beta) to broader market momentum—while it underperforms significantly during bearish contractions, it offers asymmetric upside during liquidity expansion cycles.

5. Strategic Portfolio Construction & Recommendations

Based on the empirical risk-return metrics gathered over the 12-month evaluation period, we propose the following guidelines for structuring a resilient cryptocurrency portfolio:

- **Core-Satellite Asset Allocation:** Investors should maintain a dominant core allocation of **60% – 70% in Bitcoin (BTC)** to anchor portfolio volatility and mitigate severe capital drawdowns.
- **Tactical Growth Allocation:** Allocate **20% – 25% to Ethereum (ETH)** to capture ecosystem yield and decentralized infrastructure growth with moderate relative risk.
- **Asymmetric Satellite Exposure:** Cap exposure to **Solana (SOL) at 10% – 15%**. This limits maximum portfolio drawdown while preserving exposure to high-beta upside during bullish trend reversals.
- **Execution Strategy (Dollar-Cost Averaging):** Given the significant volatility across all three assets (as demonstrated by the spread between 52-week highs and lows), lump-sum deployment is discouraged. Implementing systematic **Dollar-Cost Averaging (DCA)** over 4 to 6 months effectively averages the entry basis and cushions downside risk.
